ABSTRACT:

An aromatic polyamide film, which is a laminated film comprising at least two layers characterized in that at least one outermost layer (A) of the film

BEST AVAILABLE COPY

is one made from a mixture comprising an aromatic polyamide and one or more other polymers, has a content of the other polymers of 0.1 to 10 wt.%, and satisfies the relationships: $0.01 \leq t/d \leq 0.5$, $0.05 \leq s/L \leq 1$ (wherein d represents the thickness (μm) of the layer (A); t represents the diameter (μm) of the equivalent circle of the other polymers; and L and s represent the major and minor axes (μm) thereof, respectively). The film is free from creasing and telescoping in the wind-up step and is excellent in surface wear resistance, thus being particularly useful as a high-productivity base film for magnetic recording media.
